

How Many Ways To Insert JS

JavaScript, also known as JS, is one of the scripting (client-side scripting) languages, that is usually used in web development to create modern and interactive web-pages. The term "script" is used to refer to the languages that are not standalone in nature and here it refers to JavaScript which run on the client machine.

1. internal JS:

By using script tag at the bottom of the document

Syntax:

```
<body>
  <script>
    Console.log("hello world");
  </script>
</body>
```

2. inline JS:

we can apply inline js within the element.

Syntax:

```
<body>
  <button onclick="alert('hello world')">click</button>
</body>
```

3. external JS:

By creating a js file with .js extension we can insert js file into the html document. That js file is linked in the script tag.

Syntax:

```
<body>
  <script src="js file with .js extension"></script>
</body>
```

Variables:

Variables are used to store data in JavaScript. Variables are used to store reusable values. The values of the variables are allocated using the assignment operator("=").

Variable is used to Store Data

JavaScript Variables can be declared in 4 ways:

- **Automatically**
- **Using var**
- **Using let**
- **Using const**

Example:

```
a=10;  
Var b=20;  
let c=5;  
Const d=15;  
console.log(a); //10  
console.log(a); //20  
console.log(a); //5  
console.log(a); //15
```

Rules for Identifiers:

- Names can contain letters, digits, underscores, and dollar signs
- Identifier should not start with number
- Names must begin with a letter or `_` or `$`
- Names are case-sensitive
- Reserved words cannot be used as Identifier.

Terms:

Dynamic typing:

Js is a dynamically typed, meaning you do not have to specify the datatype of the variable when declared. The Data type of the variable is determined automatically in a runtime.

Hoisting

- It is a behaviour where the **declaration of the variable and functions are moved to the top** even before the execution.
- Only Declaration is hoisted not the Initialization
- Only works in **var** remaining **let** and **const** goes to temporary deadzone

Example:

```
a=20;  
Console.log(a); //20  
  
var a;
```

Data types

JavaScript provides different **data types** to hold different types of values. There are two types of data types in JavaScript.

Primitive Data Types:-

Primitive data types are the fundamental building blocks used to represent single values.

- Primitive data types which is stored in stack. ^{value} (call by value & pass by ~~reference~~)
- which are immutable. we can access the data but cannot change.

Non Primitive Data types:- (or) Composite data type

- Used to represent multiple values
- non primitive data types are stored in heap. (call by reference & pass by reference)
- which are mutable (we can change data).

Primitive

- Number :- represents numeric values

Eg:- `var a = 100;`

- String :- represents Group of characters

Eg:- `var b = "Hello"`

- Boolean :- represents boolean value either

true - 1 or false - 0

- Null :- represents null, i.e. no value at all (intentionally Empty value)

- Undefined :- variable with out value (declared but not assigned value)

Non primitive

- array :- represents group of similar elements
- Objects :- represents instance through which we can access members.
- functions :- it is a block of code to perform particular task and it is reusable.
- date
- reg exp :- represents regular expressions.

Examples :-

Primitive

```
var a = 20; // number
```

```
var b = 'hello'; // string
```

```
var c = true; // boolean
```

```
var d = false
```

```
var e = null
```

```
var f = undefined
```

```
console.log(c+f); // NaN
```

non primitive

arrays (number index)

```
var a = [20, 'hello', true];
```

```
a[0] = 30;
```

```
console.log(a); // [30, 'hello', true]
```

```
console.log(a[-1]);
```

objects (named index)

```
var b = {
```

```
  id: 1201,
```

```
  name: 'Abhi',
```

```
  age: 22
```

```
}
```

```
console.log(b.age); // 22
```

date:-

```
var c = new Date();
console.log(c);
```

function:-

```
var d = function () {
    console.log('hello world');
}
```

Typeof:

The typeof operator returns the data type of a variable.

The JavaScript typeof operator returns the data type of a variable or expression. It's a unary operator placed before its operand and returns a string indicating the data type, such as "number", "string", "boolean", "object", "undefined", "function", or "symbol".

The screenshot shows a web browser window with the address bar displaying '127.0.0.1:5500/Day-2/task.html'. The browser's console shows the output of the JavaScript code. On the left, a code editor displays the following code:

```

12 <html lang="en">
13 <body>
14
15
16 <script>
17     var a=10;
18     let b=20;
19     const c=30;
20
21     console.log(a);
22     console.log(b);
23     console.log(c);
24
25
26     var num=23;
27     var str='Abhi';
28     var bool=true;
29     var ud=undefined;
30
31     console.log(typeof num); //number
32     console.log(typeof str); //string
33     console.log(typeof bool); //boolean
34     console.log(typeof ud); //undefined
35     console.log(typeof 10); //num
36
37     console.log(typeof null); //null repr
38
39 </script>
40
41

```

The browser's console shows the following output:

```

10 task.htm
20 task.htm
30 task.htm
number task.htm
string task.htm
boolean task.htm
undefined task.htm
number task.htm
object task.htm
>

```
